

Cost and Return Estimates of a Mamey Sapote Grove in South Florida, 2017¹

Fredy H. Ballen, Aditya Singh, Edward A. Evans, and Jonathan Crane²

Introduction

Figure 1. Mamey sapote.
Credit: USDA

Mamey sapote (*Pouteria sapota*), originally from Mexico and Central America, is a tropical fruit tree cultivated in Central America, South America, and the Caribbean. It can be grown in subtropical conditions, but it is sensitive to freezing temperatures. The fruit was first reported in Florida by Pliny Reasoner in 1887. After several introductions from the Caribbean during the early twentieth century and an influx of Cuban Americans to Florida, a small but vibrant mamey sapote industry began in the mid-1970s in south Florida (Morton 1987; Pantin 1991). Commercial production of mamey sapote in the United States is limited to south Florida, mainly Miami-Dade County. The United States also imports a limited amount of fruit from Puerto Rico, with the main destination being the Boston market.

The 'Magaña' and 'Pantin' cultivars make up 95% of the total area cultivated (about 500 acres) in south Florida (Figures 2 and 3). An established orchard (7 years and older) may yield up to 18,000 to 22,000 pounds of fruit per acre (Goenaga and Jenkins 2012), but after considering biannual fluctuations in crop yield, annual average yield is usually about 9,000 pounds per acre. The average Homestead free on board price (F.O.B.) in 2016 was \$1.17 per pound (the F.O.B. price is the final price yielded to the

growers after meeting all the supply side costs). Hence, the crop is worth upwards of \$5.2 million at the farm gate level.

There is little information on the production costs and returns of minor tropical fruit crops, so our objective is to provide an estimate of the costs and returns associated with an established mamey sapote orchard in south Florida. Our information was obtained from field interviews with industry experts and with growers

cultivating the fruit in small acreages (1–3 acres) in south Florida. The information presented reflects a wide variety of production practices, and it is intended only as a guide to estimate the financial requirements of maintaining a mamey sapote grove. Readers interested in specific information about the cultural practices of mamey sapote may wish to peruse FC-30, *Mamey Sapote Growing in the Florida Home Landscape* by Balderi et al. (2008) (<https://ask.ifas.ufl.edu/publication/MG331>).

Main Assumptions

Most of the growers in south Florida already own the land, so a rental cost of \$550 per acre per year is used in this analysis to reflect the opportunity cost of land. The budget and production cost items are based on a one-acre orchard on a per-year basis. Given the wide diversity of cultural practices and managerial styles among the growers interviewed, we report average costs and prices for the present analysis.

Orchard Layout

In south Florida, mamey sapote plantings are typically spaced 25 to 30 feet between-rows and 15 to 20 feet in-rows (between trees), resulting in a planting density of 75 to 145 trees per acre (Mossler and Crane 2013). For this analysis, we consider a density of 116 (25x15 spacing) trees per acre.

Yields

On the basis of information provided by the growers, average marketable yields are about 9,847 pounds per acre per year.

Mamey Sapote Prices

The average F.O.B. (Homestead) price for mamey sapote is estimated at \$1.17 per pound. This estimate is calculated from the prices received by growers from packinghouses during 2016.

Irrigation

Adequate water supply is critical during flowering, fruit set, and early fruit development. Mature trees should be watered once or twice per week with 1 inch (2.5 cm) of water during periods of insufficient rainfall (Balderi et al. 2008). Average irrigation expenses composed of fuel/electricity costs are estimated at \$94/acre/year.

Fertilization

Conventional fertilizer practices include applications of 8-3-9 (NPK) or a similar fertilizer material, foliar-applied micronutrients (e.g., manganese, zinc, and boron), and soil-drench applications of chelated iron. Average fertilization costs (materials only) are estimated at \$95/acre/year.

Pest Management

Few insects and diseases attack mamey sapote, so the level of damage does not always require control. The most common pests include leafhoppers (Order Hemiptera) feeding on immature leaves, Cuban May beetle (*Phyllophaga bruneri*) feeding on the leaves during the summer months, sugarcane rootstalk borer (*Diaprepes abbreviatus*), and various scales such as the white peach scale (*Pseudaulacaspis pentagona*), philephedra scale (*Philephedra* sp.), and wax scales (*Ceroplastes* sp.). Mamey sapote diseases include anthracnose (Penz), which may damage flowers and young leaves; red alga (*Cephaleuros virescens* Kunze), which attacks twigs and limbs; and root diseases (*Rhizoctonia* sp., *Pythium splendens*) (Balderi et al. 2008). Average agrochemical costs (materials only) include herbicides (\$87/acre/year), insecticides (\$137/acre/year), and fungicides (\$123/acre/year).

Labor Costs

These include agricultural input application costs (e.g., fertilizers and agrochemicals) and cultural operation costs (e.g., irrigation management and repair, pruning, and mowing vines). Labor costs are estimated at \$569/acre/year.

Interest on Operating Capital

This is the cost of borrowing money or the opportunity cost for using equity. A rate of 5% is used in the present analysis.

Fixed Overhead Costs

These represent fixed expenses to operate a farm. The costs include cash overhead costs (insurance and taxes), non-cash overhead costs (land rent) and other overhead costs (machinery depreciation, interest, electricity, telephone, computer, and other office expenses). Fixed overhead costs are estimated at \$1,112/acre/year.

Harvesting and Marketing Costs

Harvesting mamey sapote is a very labor-intensive process because each fruit must be individually tested for maturity before harvesting. For commercial purposes, the fruit is considered horticulturally mature for harvest when the pulp has a reddish color. The cost of picking, packing, and sales is estimated at \$1,454/acre/year (\$0.15 per pound).

The total expenses and returns associated with an orchard in full production includes operating costs, fixed costs, and harvesting and marketing costs (Table 1). The various components include operating costs, fixed overhead costs, and harvesting and marketing costs.

- **Operating Costs** or variable costs total \$1,160/acre/year (about \$0.12/lb.), representing 31% of total cost. The major cost components within this category are hired labor (49%), insecticides (11%), and fungicides (10%).

- **Fixed Overhead Costs** include insurance, property taxes, other overhead charges (electricity, insurance, telephone, etc.), and land rental. Although growers already own the land, the land rental charge of \$550/acre/year reflects the opportunity cost of the land. Fixed costs are estimated at \$1,112/acre/year.
- **Harvesting and Marketing Costs** are estimated at \$1,454/acre/year (\$0.15/lb.), representing 39% of total cost of production. Harvesting the fruit is a time-consuming process because each fruit must be inspected for maturity before harvesting.

The total cost structure for mamey sapote production and the respective share of its components are shown in Figure 4. Harvest and marketing costs are the major cost drivers, accounting for 39% of total cost, followed by operating costs (variable costs for pruning, fertilization, and pest control) at 31%, fixed overhead costs at 29%, and interest on capital at 1% of total cost.

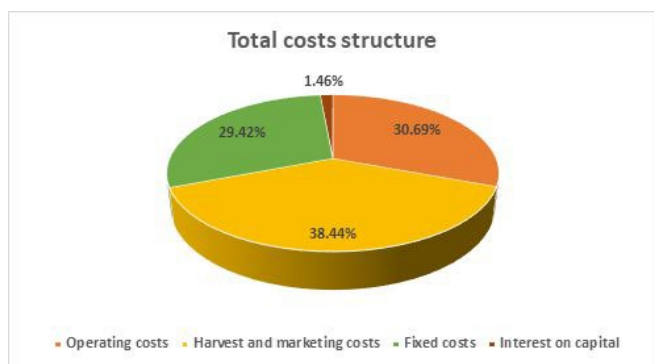

Figure 4. Total cost structure.

Returns and Profitability Analysis

Based on the information provided by the growers, the average marketable yield is about 9,847 pounds/acre/year. Assuming a planting density of 116 trees/acre, per-tree yield is about 90 pounds.

Using the average F.O.B. Homestead price of \$1.17/pound, total **revenue** is \$11,521/acre/year. Subtracting total variable cost (total operating cost plus harvesting and marketing cost) from total revenue results in a **gross margin** (\$11,521-\$2,614) of \$8,907/acre/year. The gross margin provides an indication of short-term profitability. A positive gross margin implies that all variable costs have been covered and there are additional funds remaining to cover some or all of the fixed overhead costs. Following this approach implies a return of \$0.90/pound compared to other south Florida crops such as avocado (\$0.15/pound). Note that profitability based on the gross margin is not a true reflection of the long-term profitability of the business.

Many growers are only concerned with the gross margin. However, a more realistic approach is to calculate the **net return**, which also considers the fixed overhead costs. The

net return is \$7,795/acre, or \$0.79/pound; this is still attractive compared to the returns obtained from other tropical fruits in the area.

Sensitivity Analysis

A sensitivity analysis of net returns to the grower on a per-acre basis demonstrates how profitability of the operation may change with changes in yield and prices (Table 2). In a best-case scenario where both price and yield are assumed to increase by 10%, net return per acre would increase from \$7,795 to \$10,247. In a worst-case scenario where both price and yield decline by 10%, net return per acre would decrease from \$7,795 to \$5,579 per acre. Other combinations of changes in prices and yields and their impact on net return per acre are shown in Table 2. However, it should be noted that at the industry level, a noticeable increase in production usually results in a decrease in the price received by the growers. A similar analysis conducted on the basis of gross margin (gross profit) may be interpreted in a similar manner as in Table 2, noting that this is with respect to gross profit, which ignores the fixed cost estimates (Table 3).

Conclusions

Our estimate of total annual production cost for mamey sapote in south Florida is \$3,726/acre, or about \$0.38/pound. A gross revenue of \$11,521/acre (\$1.17/pound) results on a net return to the grower of about \$7,795/acre, or \$0.79/pound, which makes this tropical fruit crop an interesting option. It is important to point out that the information presented here refers to established groves. Assessing the profitability of establishing a new mamey sapote grove includes additional budget considerations: land acquisition, establishment of the grove, and financing for capital investment are all added costs. Also, the exotic fruit market is considered a niche market, with oversupply resulting in a precipitous fall in prices. As a precaution, potential investors should proceed with care before starting any new enterprises.
