

Scouting for Insects, Use of Thresholds, and Conservation of Beneficial Insects on Tomatoes¹

David J. Schuster and Hugh A. Smith²

Integrated pest management (IPM) can be defined as the utilization of all available tactics for managing pests such that economic loss is avoided and environmental impact minimized. The cornerstone of IPM is knowledge of the pests attacking a crop and an understanding of the relationship of density of those pests to crop damage. Therefore, every IPM program is dependent upon periodic scouting to ascertain pest density and upon establishment of densities when treatment is warranted, i.e., thresholds. Although thresholds based upon the economics of the crop and upon the cost of treatment have been developed for some pests of vegetables, these "economic" thresholds generally have not been used because of the variability and unpredictability of the ultimate market value of fresh market vegetables. Therefore, action thresholds have been utilized. Action thresholds can be defined as those levels of pest density or damage that result in consistently (statistically) measurable losses in yield quantity or quality. What follows is a description of the rationale of scouting methodology, action thresholds, and pesticide selection criteria for tomatoes.

Many pests attack tomato in Florida (University of Florida 2006). The whitefly attacking tomato in Florida is the silverleaf or sweetpotato whitefly, *Bemisia tabaci* biotype B (Figure 1). Silverleaf whitefly transmits *Tomato yellow leaf curl virus*, and nymphal feeding causes irregular ripening of fruit. Thrips attacking tomato include western flower thrips, *Frankliniella occidentalis* (Figure 2), and the melon thrips, *Thrips palmi*. Thrips transmitted viruses affecting tomato include *Tomato spotted wilt virus* (TSWV), *Ground nut ring spot virus*, and *Tomato chlorotic wilt virus*. Aphids attacking tomato include the green peach aphid (*Myzus persicae*) and the potato aphid (*Macrosiphum euphorbiae*). Tomatoes are fed on by several types of caterpillars, including armyworms, loopers, and the tomato pinworm (*Keiferia lycopersicella*). *Liriomyza trifolii* is the most common leafminer attacking tomato in Florida; *L. sativae* is also present. The twospotted spider mite (*Tetranychus urticae*) (Figure 3) and tomato russet mite (*Aculops lycopersici*) (Figure 4) are also pests of Florida tomato.

Scouting Methodology

Scouting methods should not only take into account the relative density and distribution of pests but also the stage of growth of the plant. In tomato, the area of each field is measured, and two-acre grids are established. A sample is taken from 6 contiguous plants in each grid to ensure that every area of the field is sampled. For whiteflies, 10 contiguous plants are sampled because whitefly populations tend to be more clumped than other pests. The numbers of whiteflies, aphids, lepidopterous eggs, and living and dead leafminer larvae (Figure 5) are counted either on the whole plant or on the terminal leaflet(s) of the 3rd or 7th leaf from the top of the main stem or lateral branches, depending upon crop phenology (Table 1). This procedure takes into account that the distribution of leafminer larvae and whitefly nymphs (Figure 6) on leaves moves up the plant as it grows, and that most larvae and nymphs occur on leaves 6 to 10, counting from the top. Counting from the

top ensures that the leaf selected for sampling is consistently of the same age, regardless of plant age or stem status (i.e., main, lateral or even sub-lateral stems), and consistently in the region of the plant where most larvae or nymphs occur.

To determine whether leafminer larvae are dead or alive, leaflets are removed from the plant, held up to the sun, and examined with a hand lens. Living larvae are a pale yellow and flush with the end of the mine. The back and forth feeding movements of the mouth hooks are readily visible, although movement may cease momentarily

when larvae are disturbed or may cease for an extended time when larvae are molting. Dead larvae do not show mouth hook movement and are usually discolored and removed from the ends of mines. Determining whether whitefly nymphs are alive or dead is more difficult and subjective. Living nymphs are usually clear and contain paired yellow mycetomes, whereas dead nymphs are usually discolored and contain orange mycetomes. They may appear collapsed, especially if fed upon by predators.

Yellow sticky traps can be used for estimating relative densities of leafminer and whitefly adults but are most useful in determining changes in adult densities over time. Whitefly adults may be sampled by carefully turning over the 3rd leaf from the top and counting the whiteflies present. Morning sampling is best because whitefly adults become more easily disturbed and, hence, put to flight as the temperature increases during the day. Leafminer adults occur on the upper leaf surfaces and are most abundant on the upper third of the plant. They can be readily observed without disturbing the plant.

Whole plants are examined for noctuid larvae and true bugs, with the focus of the former being recently damaged foliage (Figure 7). After fruit set, 10 fruit per site are examined for damage. Tomato pinworm larvae are counted either on the foliage of whole plants or on one leaf selected from the lower canopy of each plant. To sample thrips, 15 flowers are selected and the numbers of thrips escaping after exhaling on the flowers and tapping them on the palm or a piece of paper are counted.

Action Thresholds

The action thresholds for tomato also take into account crop phenology (Table 1). The thresholds for aphids, whiteflies, and thrips are applied to inhibit population buildup or fruit damage or to maintain fruit quality, but not to avoid virus transmission. Prior to the appearance

of the western flower thrips and the virus it transmits, *Tomato spotted wilt virus*, the primary concern was bloom abscission. The threshold for "halo spotting" of fruit, caused by oviposition of the western flower thrips, is one-third of the flowers infested. The threshold of 5 nymphs/10 leaflets for the silverleaf whitefly was developed to time applications of the insect growth regulators buprofezin (Courier, IRAC Mode of Action Group 16) and pyriproxyfen (Knack, IRAC Mode of Action Group 7A) in order to avoid the irregular ripening fruit disorder caused by feeding of nymphs.

Spirotetramat (Movento) and spiromesifen (Oberon) are both IRAC Mode of Action Group 23 insecticides that can be used to suppress whitefly nymphs on tomato. In general, applications of insecticides to control aphids or thrips have not been successful in reducing incidence of the viruses these insects transmit. However, insecticide applications have reduced the in-field spread of insect-transmitted viruses, especially those vectored by whiteflies.

Conservation of Natural Enemies

At least 14 species of hymenopterous (wasp) parasitoids attack *Liriomyza* spp. leafminers on nonsprayed tomatoes in Florida; however, four parasite species predominate: *Diglyphus intermedius* (Girault), *D. begini* (Ashmead), *Neochrysocharis* (= *Chrysonotomyia*) *punctiventris* (Crawford), and *Opius dissitus* Muesebeck. Up to 90% parasitism in nonsprayed tomatoes has been observed in Florida. In commercial tomatoes using selective insecticides to kill leafminers and conserve parasites, parasitism can reach 100%. The tomato pinworm is attacked by a number of parasites in Florida including *Apanteles dignus* Muesebeck, *A. scutellaris* Muesebeck, *Temelucha* spp., *Sympiesis stigmatipennis* Girault, and *Trichogramma pretiosum* Riley. Parasitism in commercial fields can range from 40-60%, with the higher rates occurring later in the crop. Egg parasitism ranges as high as 60-90%, with the higher rates occurring at lower egg densities. The silverleaf whitefly is attacked by at least 15 species of parasites and 19 species of predators in Florida. A relatively small number of parasites predominate, with *Encarsia pergandiella* Howard, *Eretmocerus* sp., and *Encarsia nigricephala* Dozier being the most abundant. The minute pirate bug, *Orius insidiosus* (Say), and the lacewing, *Ceraeochrysa cubana* (Hagen), were among the most numerous predators. Parasitism of the whitefly on vegetables grown on a southwest Florida organic farm has reached up to 80% while combined parasitism and predation in nonsprayed weeds has resulted in up to 100% mortality.

The relative toxicity of selected pesticides to parasites of leafminers and the tomato pinworm and to parasites and predators of the silverleaf whitefly are shown in Tables 2 and 3. Some pesticides, like methomyl, are highly toxic to all lifestages of all natural enemies evaluated while others, like methamidophos, are highly toxic to some life

stages of natural enemies but not all. Some insecticides like azadirachtin were moderately toxic to some life stages and relatively non-toxic to most others while others, like *Bacillus thuringiensis* and cyromazine, were relatively non-toxic to all life stages of all natural enemies evaluated. Therefore, it is important that the scouting program include not only an assessment of the pests present but also the natural enemies, including the specific life stage(s). If these guidelines are followed, conservation of natural enemies through the use of timed applications of selective insecticides for the above pests can not only be feasible but can be a reality.

Tables

Table 1. Sampling methods and action thresholds for management of arthropod pests of tomatoes in Florida.

Arthropod pests	Crop phenology	Sampling method*	Threshold
Aphids	0-2 true leaves >2 true leaves	Whole plant inspection Terminal 3 leaflets of 3rd or 7th leaf from top	3-4/plant
Armyworms, fruitworms	Pre-bloom Post-bloom	Whole plant inspection Whole plant inspection Inspection of 10 fruit Terminal 3 leaflets of 3rd or 7th leaf from the top	1 larva/6 plants 1 egg or larva/sample
Leafminers	0-2 true leaves >2 true leaves	Whole plant inspection Terminal 3 leaflets of 3rd or 7th leaf from top	1 live larva/plant 1 live larva/3 terminal leaflets
Loopers	Season-long Post-bloom	Whole plant inspection Inspection of 10 fruit	1 larva/6 plants
Spider mites	Season-long	Terminal 3 leaflets of 1 leaf from lower canopy	10 mites/leaflet
Thrips, Western flower	Bloom	Exhaling on 15 flowers	>0.33 of flowers infested
Thrips, other	Bloom	Exhaling on 15 flowers	>5/flower
Tomato pinworm	0-7 true leaves >7 true leaves	Whole plant inspection One leaf from lower canopy	0.7 larva/plant 0.7 larva/plant
True bugs	Post-bloom	Whole plant inspection Inspection of 10 fruit	1 nymph or adult/plant
Whiteflies	0-3 true leaves >3 true leaves	Whole plant inspection Terminal leaflet of 3rd (adults) or 7th (nymphs or pupae) leaf from the top	1 adult/plant** 1 adult/leaflet** 5 nymphs/10 leaflets
* The method was applied to one six-plant sample per two acres.			
**If the source of whiteflies is tomato, especially tomato infected with TYLCV, the thresholds would be lower.
